Wireless TCP

W.int.2-2

- ✧ Internet + wireless + mobility
- ✧ Mobile IP: network layer, module W.int.1
- ✧ Wireless TCP: transport layer
 - TCP mechanism
 - TCP mechanism with wireless & mobility
 - Split connection & Indirect TCP
 - Snoop TCP
- ✧ End of module W.int.2
- ✧ WAP: application layer, module W.int.3

W.int.2-3

TCP mechanism

- ✦ TCP is designed for
 - ❑ Fixed end-systems
 - ❑ Stationary, wired networks
- ✦ TCP congestion control in non-wireless networks
 - ❑ Packet loss typically due to (temporary) overload situations
 - ❑ Router has to discard packets when the buffers are full
 - ❑ TCP detects congestion only indirect via missing ACKs or duplicated ACKs.
- ✦ However, such presumption can be totally non true with wireless + mobile
 - ❑ Packet loss due to commonly high transmission errors
 - ❑ Packet loss due to change of network

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-4

TCP mechanism

- ✦ Review: TCP **slow-start** algorithm
 - ❑ Start with a congestion window size equal to one segment
 - ❑ Exponential increase of the congestion window up to the congestion threshold, then linear increase
 - ❑ Missing ACK causes the reduction of the congestion threshold to $\frac{1}{2}$ of the current congestion window
 - ❑ Congestion window starts again with one segment
- ✦ Review: TCP **fast retransmit/fast recovery**
 - ❑ TCP sends an ACK only after receiving a packet
 - ❑ If a sender receives duplicated ACKs for the same packet, this is due to a gap in received packets at the receiver
 - ❑ Duplicated ACKs is not as bad as missing ACKs
 - ❑ Therefore, packet loss is not due to congestion, continue with current congestion window (do not use slow-start)

W.int.2-6

TCP mechanisms: wireless & mobility

- ✧ Impacts on TCP by introducing wireless & mobility
 - wired networks:
 - packet loss due to congestions
 - Packet reordering, but not often
 - wireless networks:
 - bit errors due to wireless channel impairments
 - handoffs due to mobility
 - ❖ e.g. a MN roams from one access point to another while there are still packets in transit to the wrong access point
 - possibly congestion, but not often

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-7

TCP mechanisms: wireless & mobility

✧ Impacts on TCP by introducing wireless & mobility

- ❑ Bursts of errors may occur due to **low signal strength** or **longer period of noise**
 - More than one packet lost in TCP
 - More likely to be detected as a timeout ⇒ enter slow start!
- ❑ Delay is often very high
 - Round-trip time can be very long and variable
 - TCP's timeout mechanisms may not work well
 - Problem exacerbated by **link-level retransmission**
- ❑ Links may be **asymmetric**
 - Delayed ACKs in the slow direction can limit throughput in the fast direction

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-8

Wireless TCP mechanism

✧ TCP is a complex protocol

- ❑ Minimal support from underlying protocols
- ❑ Indirect observation of network environment
- ❑ Large number of competing flows from different hosts
- ❑ Congestion avoidance is still a research issue

✧ TCP with wireless?

- ❑ TCP does not perform well in a wireless environment where packets are usually lost due to bit errors, not congestion
- ❑ However, **TCP cannot be easily changed/modified to adapt to wireless & mobility!**

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-9

Wireless TCP mechanism

- ✧ Can we solve it at link layer? hiding wireless loss from TCP
 - ❑ FEC can be used to correct small number of errors
 - ❑ Error detection, then retransmission at link layer
 - How to detect?
 - ❖ Link layer timeout, or ACKs, NACKs.
- ✧ Can we solve it at transport layer?
 - ❑ Split connection
 - ❑ TCP-aware link layer retransmission

Wireless TCP: split connection

W.int.2-11

Split connection

- A single TCP connection split into one connection on the wired part of route and one over wireless part of the route
 - If wireless link is not last on route, then more than two TCP connections may be needed
- Connection between wireless host **MH** and fixed host **FH** goes through base station **BS**
 - $FH-MH = FH-BS + BS-MH$

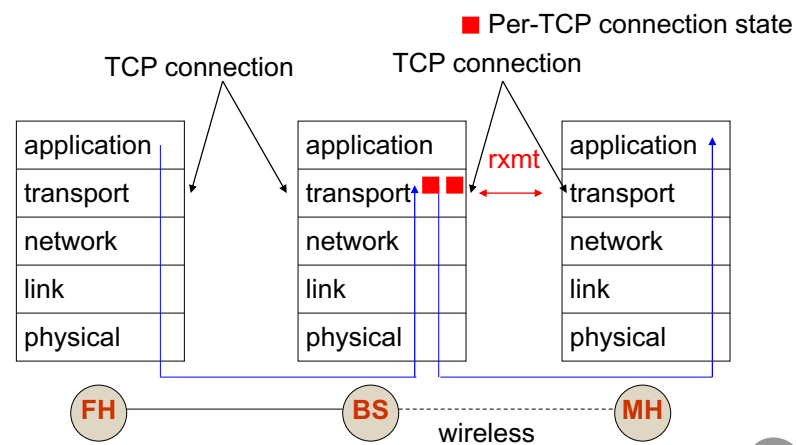

© by Dr.Wu@SJTU & Dr.Shu@UNM

Wireless TCP: split connection

W.int.2-12

Split connection protocol structure

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-13

Wireless TCP: split connection

✧ Split connection

- Split connection results in independent flow control for the two parts
 - Flow/error control protocols, packet size, time-outs, may be different for each part
- $FH-MH = FH-BS + BS-MH$, primary responsibility at base station
 - FH-BS: regular TCP
 - BS-MH: a protocol optimized for wireless link
 - ❖ Indirect TCP (I-TCP), Bakre 1995
 - ❖ Asymmetric transport protocol (Mobile-TCP), Haas 1997
 - ❖ Selective repeat protocol (SRP) on top of UDP, Yavatkar 1994

W.int.2-14

Wireless TCP: split connection

✧ Typical work:

Indirect TCP

- A. Bakre and B. Badrinath, **I-TCP: Indirect TCP for Mobile Hosts**, 15th Int'l Conf. on Distributed Computing Systems (ICDCS), 1995.
- A. Bakre and B. Badrinath, **Implementation and performance evaluation of Indirect TCP**, IEEE Trans. on Computers, 46(3), March 1997.

© by Dr.Wu@SJTU & Dr.Shu@UNM

Wireless TCP: split connection W.int.2-15

✧ Indirect TCP

- No real end-to-end connection any longer: FH - BS - MH
- FH-BS: regular TCP
 - hosts in the fixed part of the network do not notice the characteristics of the wireless part
- BS-MH: optimized TCP protocol for mobile hosts

FH: fixed host

MH: mobile host

BS: base station

„wired“ Internet

„wireless“ TCP

standard TCP

© by Dr.Wu@SJTU & Dr.Shu@UNM

Wireless TCP: split connection W.int.2-16

✧ Advantages

- FH-BS: No changes in the fixed network necessary
 - All current optimizations to TCP still work
- BS-MH: connection can be optimized independently
 - Different flow/error control can be applied
 - Selective ACKs improve performance for such cases
- Local recovery of errors
 - Transmission errors on the wireless link do not propagate into the fixed network
 - Faster recovery due to relatively shorter RTT on wireless link

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-17

Wireless TCP: split connection

✱ Negative impacts

- ❑ End-to-end semantics violated
 - ACK may be delivered to sender, before data delivered to the receiver
- ❑ BS retains **hard state**
 - BS failure can result in loss of data (unreliability)
 - Hand-off latency increases due to state transfer
- ❑ Buffer space needed at BS for each TCP connection
 - BS buffers tend to get full, when wireless link slower
 - Window on BS-MH connection reduced in response to errors
- ❑ Extra copying of data at BS
 - increases end-to-end latency

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-18

Wireless TCP: split connection

✱ Indirect TCP's alternative: Mobile TCP

- ❑ Special handling of lengthy and/or frequent disconnections
 - If I-TCP, data buffered grows too large in size
 - How to improve? Informing the sender!
- ❑ M-TCP splits as I-TCP does
 - unmodified TCP fixed network to **supervisory host (SH)**
 - optimized TCP SH to MH
- ❑ Supervisory host
 - no caching, no retransmission
 - monitors all packets, if disconnection detected
 - ❖ set sender window size to 0 to advertise back to the sender
 - Resume it when MH can be connected again
- ❑ Good: maintains semantics, supports disconnection, no buffering
- ❑ Bad: loss on wireless link propagated into fixed network

W.int.2-20

Wireless TCP: snoop TCP

local retransmission at link layer

SA: snoop agent

FH: fixed host

„wired“ Internet

MH: mobile host

snooping of ACKs, buffering of data

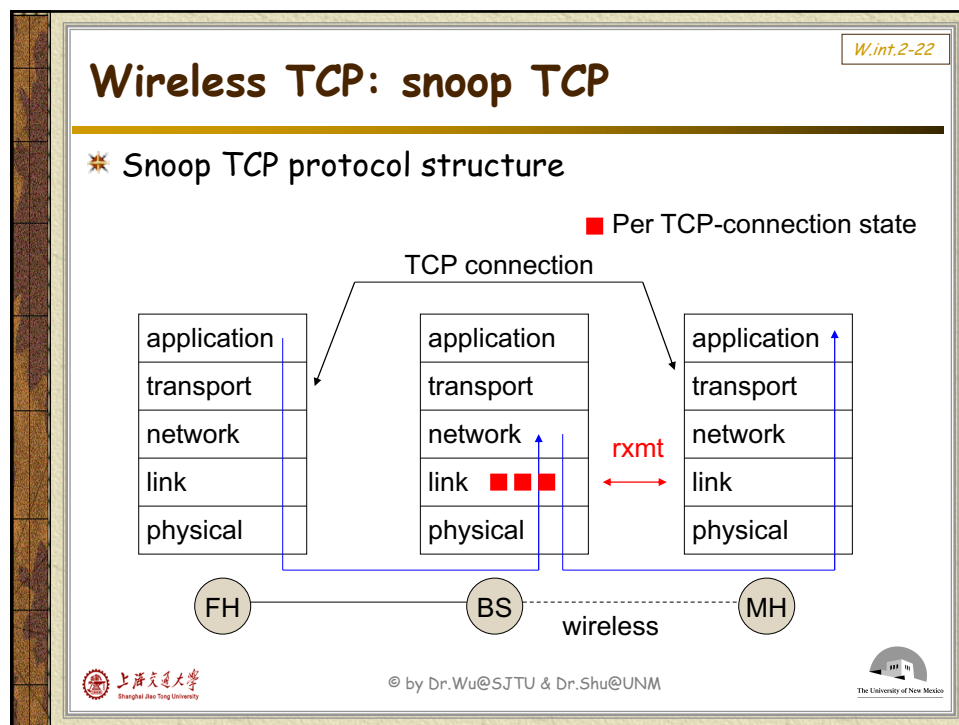

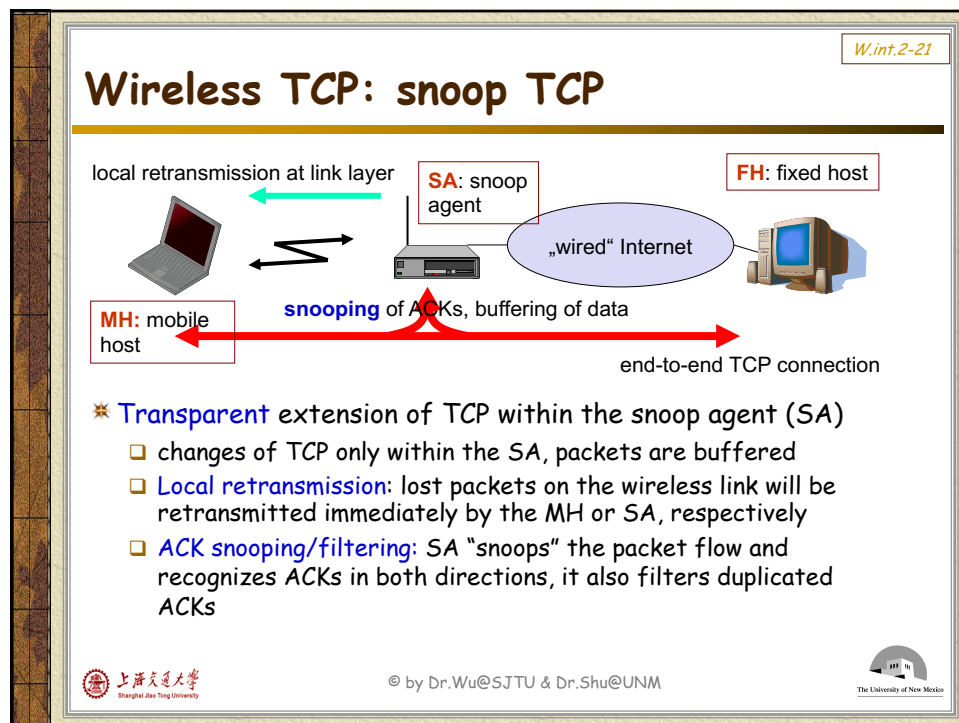

end-to-end TCP connection

- ✧ **Snoop TCP:** Hari Balakrishnan, Srinivasan Seshan, Randy H. Katz. [Improving Reliable Transport and Handoff Performance in Cellular Wireless Networks](#) ACM Wireless Networks, 1(4), December 1995.
- ✧ **Basic idea:** soft-state in BS's (the snoop agent) is used to perform local retransmissions across a wireless link to avoid end-to-end congestion control and retransmissions
- ✧ **Software:** [The Berkeley Snoop Protocol](#)

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-23

Wireless TCP: snoop TCP

- ✧ Data transfer FH \rightarrow (SA) \rightarrow MH
 - SA buffers data until it receives ACK of the MH
 - SA detects packet loss via
 - duplicated ACKs
 - ❖ SA discards duplicate ACKs from mobile host
 - time-out (can be relatively short)
 - Fast retransmission possible at link layer, transparent for the fixed network
 - SA, however, cannot generate ACKs that are sent back to FH
 - Unlike I-TCP, Snoop TCP preserves end-to-end TCP semantics

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-24

Wireless TCP: snoop TCP

- ✧ Data transfer MH \rightarrow (SA) \rightarrow FH
 - SA detects packet loss on the wireless link via sequence numbers, SA answers directly with a NACK to the MH
 - MH can now retransmit data with only a very short delay, hopefully in time to avoid a TCP timeout at FH
- ✧ Summary: provide reliable link layer that is TCP aware
 - SA at the access point or foreign agent
 - Buffers data at the ends of the links for retransmissions
 - Snooping on ACKs and filters duplicate ACKs

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-26

Wireless TCP: snoop TCP

✧ Advantages

- High throughput can be achieved
- Local recovery from wireless losses
- Fast retransmit not triggered at sender despite out-of-order link layer delivery
- Preserves end-to-end TCP semantics
- Soft state at base station
 - loss of the soft state affects performance, but not correctness
 - Automatic fallback to standard TCP
- No need to ensure that all foreign networks provide a Snoop agent

© by Dr.Wu@SJTU & Dr.Shu@UNM

W.int.2-27

Wireless TCP: snoop TCP

- ✧ Negative impacts
 - ❑ Does not isolate the wireless link as good as I-TCP
 - ❑ Violate the general layering approach
 - Link layer at base station needs to be TCP-aware
 - ❑ Snooping might be useless depending on encryption schemes
 - E.g., not useful if TCP headers are encrypted (IPsec)
 - ❑ The TCP stack on the MH had to be modified to handle NACKs for reverse (MH→FH) traffic
 - ❑ Cannot be used if TCP data and TCP ACKs traverse different paths (both do not go through the base station)
