## Random access protocols

- when node has packet to send
  - transmit at full channel data rate R.
  - no a priori coordination among nodes
- two or more transmitting nodes → "collision",
- random access MAC protocol specifies:
  - how to detect collisions
  - how to recover from collisions (e.g., via delayed retransmissions)
- examples of random access MAC protocols:
  - slotted ALOHA
  - ALOHA
  - CSMA, CSMA/CD, CSMA/CA

## Slotted ALOHA

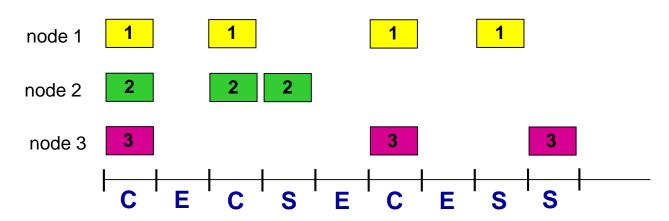

#### assumptions:

- all frames same size
- time divided into equal size slots (time to transmit I frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

#### operation:

- when node obtains fresh frame, transmits in next slot
  - if no collision: node can send new frame in next slot
  - if collision: node retransmits frame in each subsequent slot with prob. p until success

## Slotted ALOHA

#### **Pros:**

- single active node can continuously transmit at full rate of channel
- highly decentralized: only slots in nodes need to be in sync
- simple

#### Cons:

- collisions, wasting slots
- idle slots
- nodes may be able to detect collision in less than time to transmit packet
- clock synchronization

## Slotted ALOHA: efficiency

efficiency: long-run fraction of successful slots (many nodes, all with many frames to send)

- suppose: N nodes with many frames to send, each transmits in slot with probability p
- prob that given node has success in a slot =  $p(1-p)^{N-1}$
- prob that any node has a success =  $Np(1-p)^{N-1}$

- max efficiency: find p\* that maximizes
  Np(1-p)<sup>N-1</sup>
- for many nodes, take limit of  $Np^*(1-p^*)^{N-1}$  as N goes to infinity, gives:

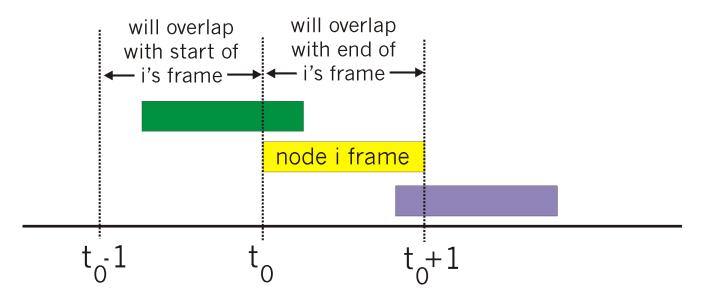

max efficiency = 1/e = .37

at best: channel used for useful transmissions 37% of time!

## Pure (unslotted) ALOHA

- unslotted Aloha: simpler, no synchronization
- when frame first arrives
  - transmit immediately
- collision probability increases:
  - frame sent at  $t_0$  collides with other frames sent in  $\begin{bmatrix} t_0 1, t_0 + 1 \end{bmatrix}$

## Pure ALOHA efficiency

P(success by given node) = P(node transmits) ·

P(no other node transmits in  $[t_0-I,t_0]$  · P(no other node transmits in  $[t_0-I,t_0]$ 

$$= p \cdot (1-p)^{N-1} \cdot (1-p)^{N-1}$$
$$= p \cdot (1-p)^{2(N-1)}$$

... choosing optimum p and then letting  $n \rightarrow \infty$ 

$$= 1/(2e) = .18$$

even worse than slotted Aloha!

## CSMA (carrier sense multiple access)

**CSMA:** listen before transmit:

if channel sensed idle: transmit entire frame

 if channel sensed busy, defer transmission

human analogy: don't interrupt others!

## **CSMA** collisions

- collisions can still occur: propagation delay means two nodes may not hear each other's transmission
- collision: entire packet transmission time wasted
  - distance & propagation delay play role in in determining collision probability

 $\mathsf{t}_{_1}$ 

## CSMA/CD (collision detection)

### CSMA/CD: carrier sensing, deferral as in CSMA

- collisions detected within short time
- colliding transmissions aborted, reducing channel wastage
- collision detection:
  - easy in wired LANs: measure signal strengths, compare transmitted, received signals
  - difficult in wireless LANs: received signal strength overwhelmed by local transmission strength
- human analogy: the polite conversationalist

# CSMA/CD (collision detection)

# "Taking turns" MAC protocols

#### channel partitioning MAC protocols:

- share channel efficiently and fairly at high load
- inefficient at low load: delay in channel access, I/N bandwidth allocated even if only I active node!

#### random access MAC protocols

- efficient at low load: single node can fully utilize channel
- high load: collision overhead

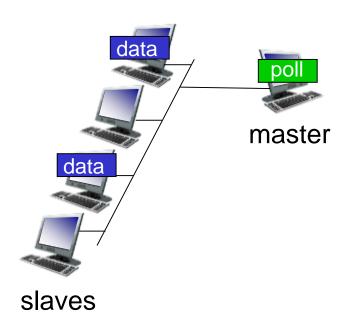

### "taking turns" protocols

look for best of both worlds!

# "Taking turns" MAC protocols

### polling:

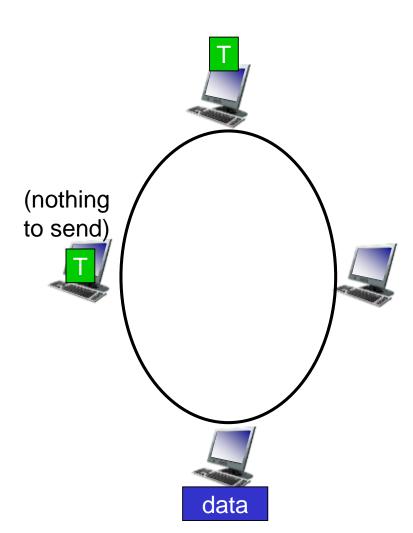

- master node "invites" slave nodes to transmit in turn
- typically used with "dumb" slave devices
- concerns:
  - polling overhead
  - latency
  - single point of failure (master)

# "Taking turns" MAC protocols

### token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
  - token overhead
  - latency
  - single point of failure (token)

## Summary of MAC protocols

- channel partitioning, by time, frequency or code
  - Time Division, Frequency Division
- random access (dynamic),
  - ALOHA, S-ALOHA, CSMA, CSMA/CD
  - carrier sensing: easy in some technologies (wire), hard in others (wireless)
  - CSMA/CD used in Ethernet
  - CSMA/CA used in 802.11
- taking turns
  - polling from central site, token passing
  - Bluetooth, FDDI, token ring

## Link layer, LANs: outline

- 6. I introduction, services
- 6.2 error detection, correction
- 6.3 multiple access protocols
- 6.4 LANs
  - addressing, ARP
  - Ethernet
  - switches
  - VLANS

- 6.5 link virtualization: MPLS
- 6.6 data center networking
- 6.7 a day in the life of a web request

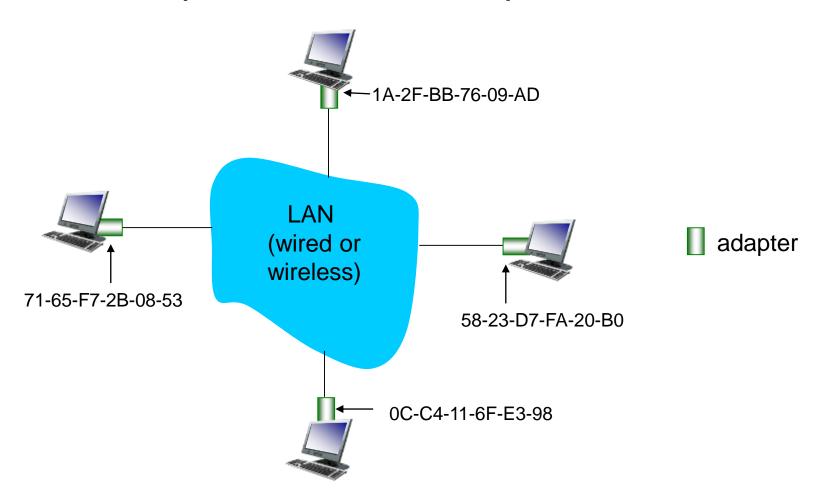

## MAC addresses and ARP

- 32-bit IP address:
  - network-layer address for interface
  - used for layer 3 (network layer) forwarding
- MAC (or LAN or physical or Ethernet) address:
  - function: used 'locally" to get frame from one interface to another physically-connected interface (same network, in IP-addressing sense)
  - 48 bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable
  - e.g.: IA-2F-BB-76-09-AD

hexadecimal (base 16) notation (each "numeral" represents 4 bits)

## LAN addresses and ARP

each adapter on LAN has unique LAN address

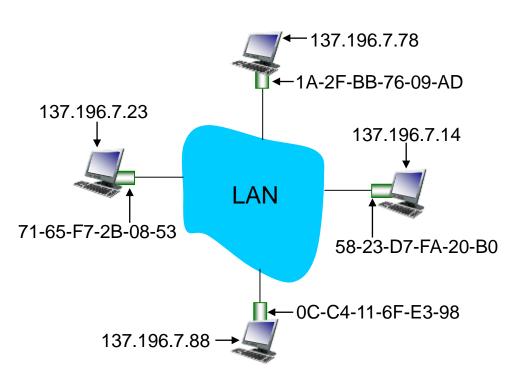

## LAN addresses (more)

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
  - MAC address: like Social Security Number
  - IP address: like postal address
- MAC flat address → portability
  - can move LAN card from one LAN to another
- IP hierarchical address not portable
  - address depends on IP subnet to which node is attached

## ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

- IP/MAC address mappings for some LAN nodes:
  - < IP address; MAC address; TTL>
- TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

## ARP protocol: same LAN

- A wants to send datagram to B
  - B's MAC address not in A's ARP table.
- A broadcasts ARP query packet, containing B's IP address
  - destination MAC address = FF-FF-FF-FF-FF
  - all nodes on LAN receive ARP query
- B receives ARP packet, replies to A with its (B's) MAC address
  - frame sent to A's MAC address (unicast)

- A caches (saves) IP-to-MAC address pair in its ARP table until information becomes old (times out)
  - soft state: information that times out (goes away) unless refreshed
- ARP is "plug-and-play":
  - nodes create their ARP tables without intervention from net administrator
